<b>14. ABSTRACT</b> One of the latest challenges being investigated by the US Army Research Laboratory's (ARL) Electronics and Radio Frequency (E&RF) Division is the development of a radar system that can accurately detect and range an electronically nonlinear target, such as a detonator of an improvised explosive device (IED). Previous nonlinear radar systems detect targets via transmission of a single frequency $\omega$ , stepping (incrementally increasing) this frequency through a wide bandwidth, and then listening for a response of the 2 <sup>nd</sup> harmonic $2\omega$ ; however, the phase information that this harmonic contains and its relationship to target distance has been largely assumed and unconfirmed. Our most recent experimental tests, both wired and wireless, have confirmed that this harmonic phase response is constant versus frequency at the target. Using inverse Fourier transforms, the range of an electronic nonlinear target can be determined from that phase.

I appreciate the mentorship of Dr Anthony Martone and Mr Kelly Sherbondy. I would also like to thank Dr Andy Sullivan, Dr Matthew Higgins, Dr Gregory Mazzaro, Mr Marc Ressler, Mr Edward Viveiros, Dr Ronald Polcawich, Mr Brian Phelan, Mr Kyle Gallagher, and Mr Roger Cutitta for their assistance and support. I also wish to acknowledge my fellow interns Richard Pooler, Kristopher Young, Jason Cornelius, and Philip Saponaro.

## **Student Bio**

---

Sean F McGowan is a senior undergraduate at Pennsylvania State University pursuing a BS degree in electrical engineering through Penn State's Schreyer Honors College. It is his first summer interning at the US Army Research Laboratory, though he has worked in Penn State's Optics & Laser Lab earlier in his undergraduate career. In the future he hopes to further his education by attending graduate school and obtaining his Masters in electrical engineering, with a focus on signal processing.

**INTENTIONALLY LEFT BLANK.**

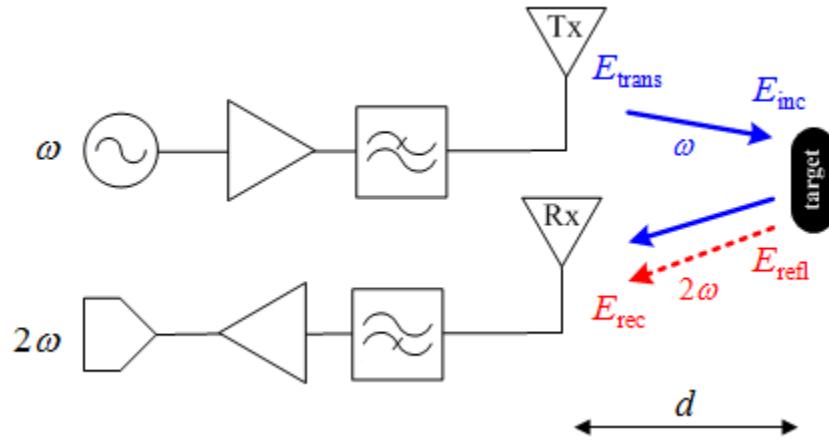

## **1. Introduction/Background**

---

Unlike its traditional, linear counterpart, nonlinear radar offers the ability to detect and range targets that contain electronically nonlinear components, such as transistors, diodes, and semiconductors. While many circuit devices, such as amplifiers, mixers, and converters, exhibit nonlinear behavior, the true potential of nonlinear radar is shown in its real-world application of detecting a range of targets from handheld radios to electronic detonators of improvised explosive devices (IEDs). Targets such as these are difficult to detect with linear radar, due to their typical size and shape – often small and thin, with a slim geometric profile. This profile lends itself to a small radar cross section, which can easily be obscured and interfered with by nearby objects or clutter. Nonlinear radar offers the feature of high clutter rejection, but this must be weighed against 2 disadvantages: 1) the harmonic response from the target is extremely weak, and thus difficult to capture, and 2) the incident power required to generate a detectable response is significantly higher than that of linear radar.<sup>1,2</sup>

The nonlinear radar model used in my experiments is akin to a harmonic, stepped frequency radar. The radar transmits a single frequency,  $\omega$ ; if the radar receives a harmonic of this fundamental (i.e.,  $2\omega$  and  $3\omega$ ), a nonlinear target is present. The original fundamental frequency  $\omega$  is then stepped, or increased by an increment  $\Delta\omega$ , across a bandwidth until enough harmonic data are collected to verify detection and calculate distance to target.<sup>3</sup>

A general diagram of harmonic radar is shown in Fig. 1. In the transmission chain, the fundamental  $\omega$  is amplified to increase its incident power on the target, and then fed through a low pass filter to attenuate any artifacts created from amplification. This signal is then transmitted to a target, and then reflected back to the receive chain, the effective reverse of the transmission chain. This time, the signal is fed through a high pass filter to attenuate the fundamental, while allowing its harmonics to pass through. The weak harmonic responses are then amplified to allow for easier detection and measurement.

**Fig. 1 General model of harmonic radar,<sup>3</sup> where transmitter = Tx and receiver = Rx**

In earlier studies of nonlinear radar, the phase of these reflected harmonics has largely been assumed to be constant versus the bandwidth of frequencies transmitted to the target.<sup>3</sup> This previously unconfirmed relationship is necessary to calculate the distance to target using an inverse Fourier transform. My experimental designs reexamine this assumption to affirm it and uphold that the harmonic stepped-frequency methods of radar are widely applicable for the detection and ranging nonlinear targets.

## 2. Harmonic Phase Response Theory

---

Let the transmitted electric field be a single-frequency sinusoid, represented as a complex exponential:

$$E_{\text{trans}}(t) = E_t e^{j\phi} e^{j\omega t} \quad (1)$$

Equation 1 shows  $E_t$  and  $\phi$  as the initial amplitude and phase of the transmitted electric field, and  $\omega$  is its fundamental frequency in radians.

As the transmitted wave travels a distance  $d$  to the target in time  $\tau$ , the amplitude of its electric field will attenuate as it propagates through the lossy medium, such as a transmission line or air. Additional, the wave will undergo a phase shift that proportional to its operating frequency. Arriving at the target, the incident electric field may be written as

$$E_{\text{inc}}(t) = E_i e^{-j\omega\tau} e^{j\omega t} \quad (2)$$

where  $E_i < E_t$ . The incident electric field incident  $E_{\text{inc}}$  can be related to the electric field that reflects off the target by the standard power series model for nonlinear, memoryless targets:<sup>12–15</sup>

$$E_{\text{refl}}(t) = \sum_{p=1}^{\infty} \tilde{a}_p E_{\text{in}}^p(t) \quad (3)$$

where  $a_p$  are complex power-series coefficients. The value of  $a_1$  is the linear response of the target, whereas the following coefficients  $\{a_2, a_3, \dots\}$  depend on a variety of properties of the device, such as the specific clutter around the device, the orientation of the target, and other radio frequency (RF) interference in the environment.

When the incident electric field described in Eq. 2 is substituted into Eq. 3, and the expanded, the result is

$$\begin{aligned} E_{\text{refl}}(t) &= \tilde{a}_1 E_i e^{-j\omega\tau} e^{j\omega t} + \tilde{a}_2 E_i^2 e^{-j2\omega\tau} e^{j2\omega t} + \tilde{a}_3 E_i^3 e^{-j3\omega\tau} e^{j3\omega t} + \dots \\ &= |a_1| e^{j\phi_1} E_i e^{-j\omega\tau} e^{j\omega t} + |a_2| e^{j\phi_2} E_i^2 e^{-j2\omega\tau} e^{j2\omega t} + |a_3| e^{j\phi_3} E_i^3 e^{-j3\omega\tau} e^{j3\omega t} + \dots \end{aligned} \quad (4)$$

This is the reflected electric field, the wave after the transmitted signal has reached the target and begins to travel back to the radar's receiver. Assuming the radar is monostatic (the transmitter and receiver are combined and thus the same distance to the target), the reflected electric field will experience a second, identical time delay of  $\tau$  on its return, so that the electric field received can be described as

$$\begin{aligned} E_{\text{rec}}(t) &= [E_1 e^{j\phi_1} e^{-j\omega\tau} e^{j\omega t}] e^{-j\omega\tau} + [E_2 e^{j\phi_2} e^{-j2\omega\tau} e^{j2\omega t}] e^{-j2\omega\tau} + \dots \\ &= (E_1 e^{j\omega t})(e^{-j2\omega\tau} e^{j\phi_1}) + (E_2 e^{j2\omega t})(e^{-j4\omega\tau} e^{j\phi_2}) + (E_3 e^{j3\omega t})(e^{-j6\omega\tau} e^{j\phi_3}) + \dots \\ &= \sum_{M=1}^{\infty} E_M e^{jM\omega t} \cdot e^{-j(2M\omega\tau - \phi_M)} \end{aligned} \quad (5)$$

In Eq. 5,  $E_M$  denotes the electric-field amplitude received at each harmonic  $M$  of fundamental frequency  $\omega$ . Each harmonic of the stepped fundamental frequency experiences a phase delay of  $2M\omega\tau - \phi_M$ . This delay is the key phase information needed to obtain range-to-target data.

If we describe Eq. 5, the electric field received by the radar, as a phasor, the result is the complex equation

$$\tilde{E}_{\text{rec}}(M\omega) = E_M \angle \{ \phi_M - 2M\omega\tau \} \quad (6)$$

To obtain distance from the equation, a simple substitution of  $\tau = d/u_p$  is required. This relationship simply states the time it takes for wave to travel to the target is the distance to the target divided by the wave's speed.

$$\tilde{E}_{\text{rec}}(M\omega) = E_M \angle \left\{ \phi_M - 2M\omega(d/u_p) \right\} . \quad (7)$$

Finally, range-to-target may be calculated by solving for the derivative of the phase of  $E_{\text{rec}}$  with respect to radian frequency of the fundamental. However, this is only true of the harmonic phase response from the target is constant versus frequency.

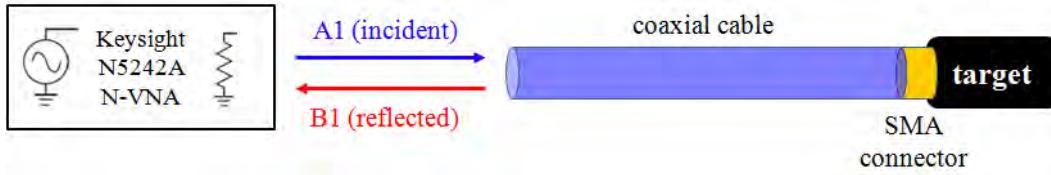

$$\begin{aligned} \angle \tilde{E}_{\text{rec}}(M\omega) &= \phi_M - 2M\omega(d/u_p) \\ \frac{\partial}{\partial \omega} \angle \tilde{E}_{\text{rec}} &= 0 - 2M \frac{d}{u_p} \\ d &= -\frac{u_p}{2M} \left\{ \frac{\partial}{\partial \omega} \angle \tilde{E}_{\text{rec}} \right\} . \end{aligned} \quad (8)$$

The experimental data collected and delineated in this study confirm that target distance can be calculated from  $E_{\text{rec}}$  using Eq. 8.

### 3. Wireline Experiment

---

To begin verification of the assumed phase-frequency relationship, a basic wireline experimental design is used, as depicted in Fig. 2. Both the radar's transmitter and receiver is simulated by using the Keysight N5242A PNA-X nonlinear vector network analyzer (NVNA). The NVNA transmits a series of stepped signals from Port 1 along 2 cascaded 12-ft MegaPhase F130 transmission lines, whose loss and distortion is known. These cables simulate the distance between the radar and a nonlinear target. The incident signal, notated as A1, reaches the target, and is reflected back into Port 1 of the NVNA, as B1.

**Fig. 2** Wireline experimental setup<sup>3</sup>

The targets used in this wireline experiment are as follows:

- MiniCircuits ZX60-3011+ amplifier (input port)
- MiniCircuits ZX60-V63+ amplifier (input port)
- MiniCircuits ZLW-186MH mixer (RF port)
- MiniCircuits ZFM-2000+ mixer (RF port)
- Motorola FV300 radio (antenna port)

- Motorola T4500 radio (antenna port)

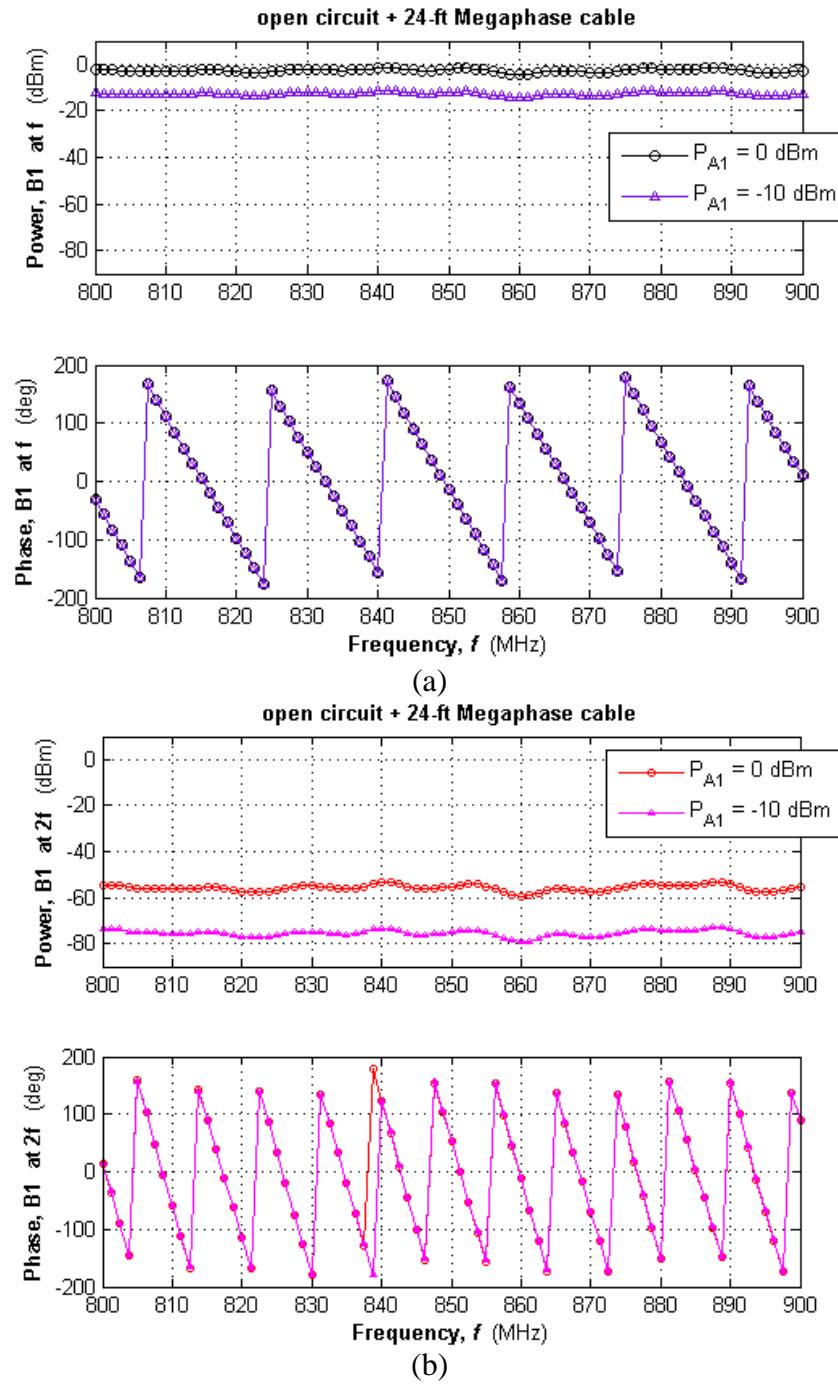

Each target had SMA input and output ports. For the amplifiers and mixers, unused ports were terminated with a  $50\text{-}\Omega$  load. For the Motorola handheld radios, their antennas were replaced with an SMA end launch soldered to their printed circuit board (PCB). Every target exhibits nonlinear behavior, with the amps and mixers typically being components to detect in a larger electronic target, and the radios more accurately representing a real-world target for a nonlinear radar system to detect.

For this wireline experiment, the previously derived distance, Eq. 8, can be simplified to account for the wave's propagation through a lossy cable like the MegaPhase F130s.

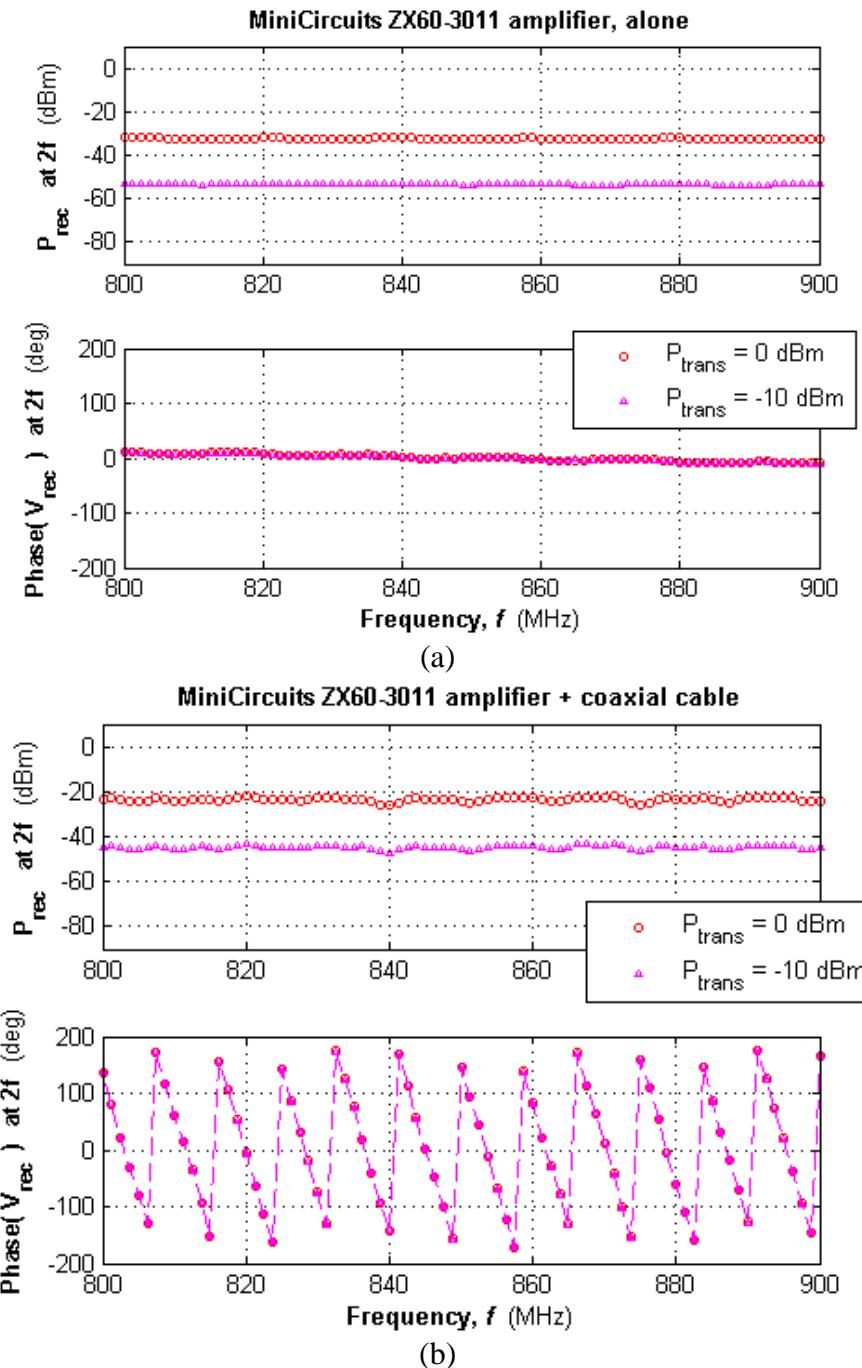

$$d = -\frac{u_p}{2M} \left\{ \frac{\partial}{\partial \omega} \angle B1 \right\} = -\frac{c/\sqrt{\epsilon_r}}{2M} \left\{ \frac{\phi_M(\omega_2) - \phi_M(\omega_1)}{\omega_2 - \omega_1} \right\} \quad (9)$$

In Eq. 9, the propagation speed has been broken down to the speed of light and the dielectric constant of the transmission line. Additionally, the derivative of the phase of the return wave has been simplified to a discrete slope equation between 2 collected data points.

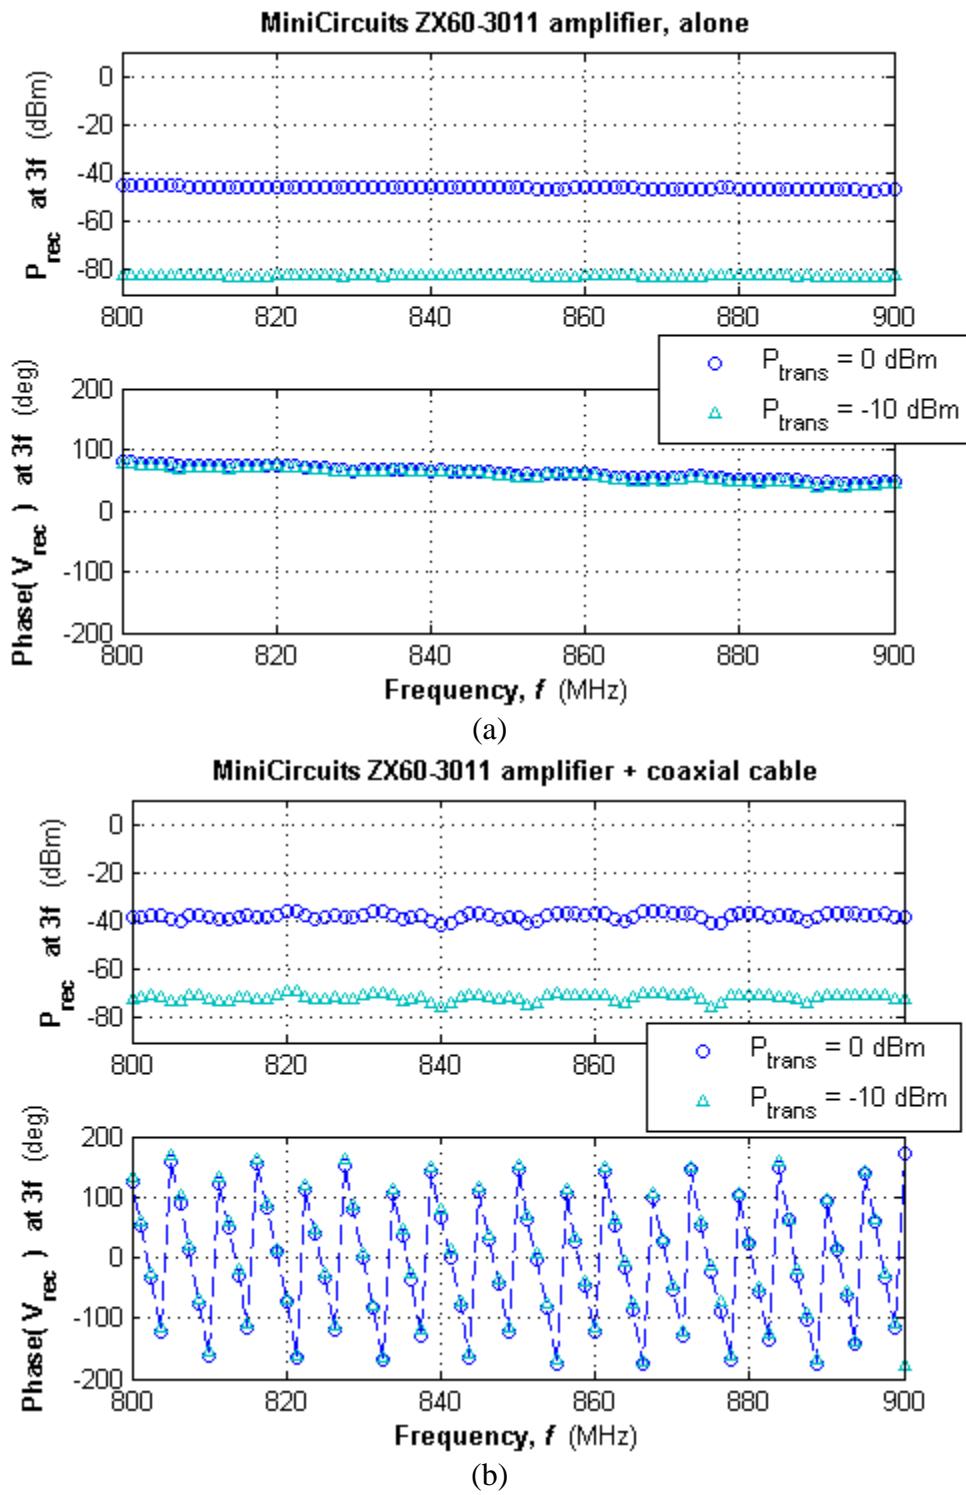

Finally, the sweep the NVNA transmits to the target is from 800 to 900 MHz with a 1.25-MHz step. Each transmitted sinusoid has the same amplitude, but is applied to the target at 2 different power levels:  $-10$  and  $0$  dBm. The results are displayed Figs. 3 through 15, with the frequency reported in Hz.

**Fig. 14** Power and phase of 2<sup>rd</sup> harmonic reflection from the Motorola T4500 radio: a) target connected to Port 1 and b) target connected through the 24-ft cable to Port 1

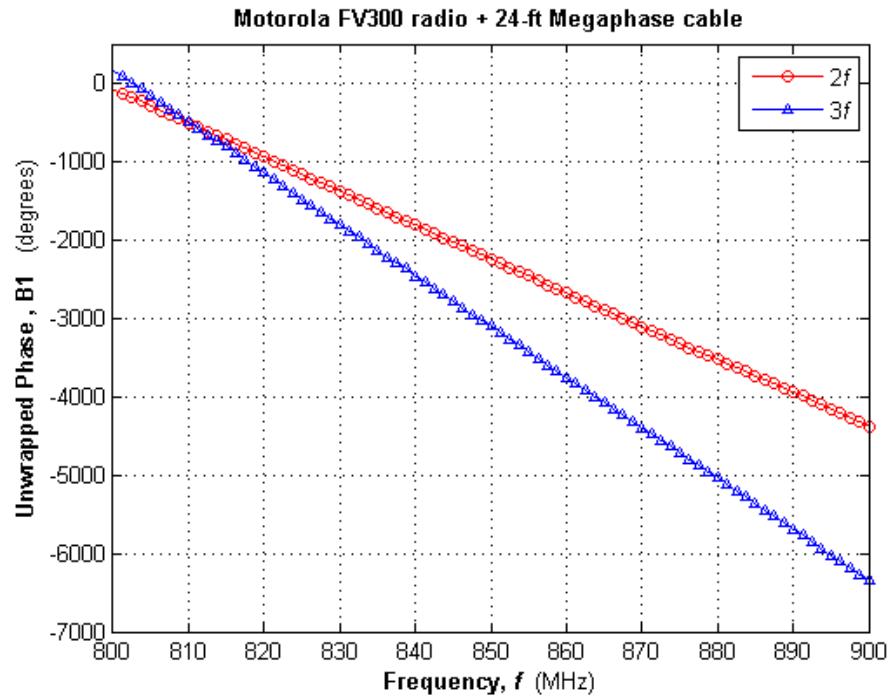

(a)

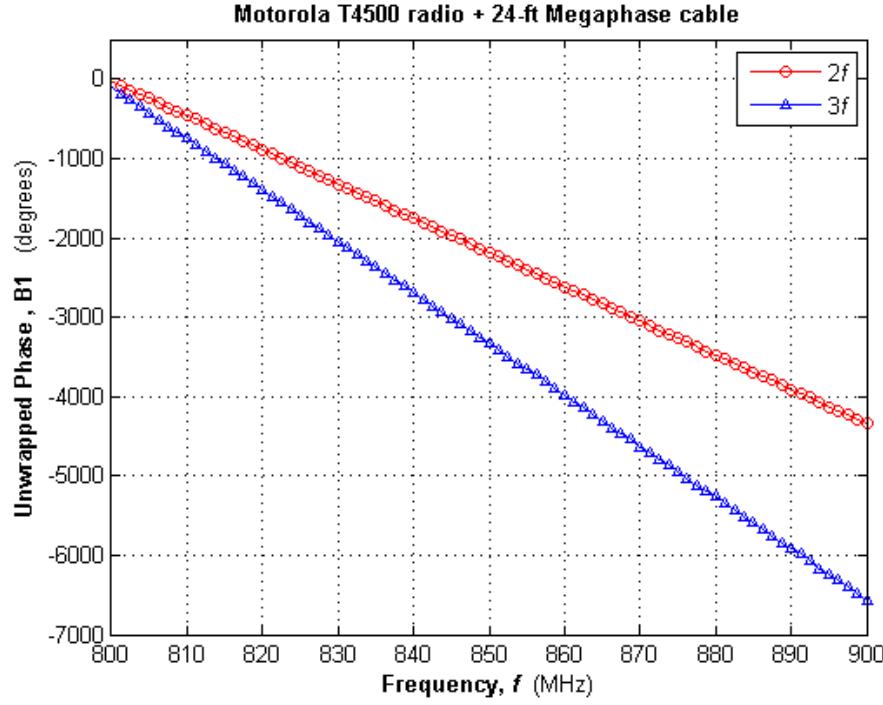

(b)

**Fig. 15** Power and phase of 3<sup>rd</sup> harmonic reflection from the Motorola T4500 radio: a) target connected to Port 1 and b) target connected through the 24-ft cable to Port 1

The assumption that harmonic phase response is constant with frequency is empirically confirmed by the data shown in Figs. 4a through 15a, which delineate a mostly flat phase response when the target is directly connected to Port 1 of the NVNA. Distance can be calculated using this phase response data at either the 2<sup>nd</sup> or 3<sup>rd</sup> harmonic of the fundamental. This is shown more clearly in Figs. 16 and 17, which contain the unwrapped phase plots for the FV300 radio (Figs. 12b and 13b) and T4500 radio (Figs. 14b and 15b), respectively, at -10 dBm.

**Fig. 16** Unwrapped harmonic phase response for the Motorola FV300

**Fig. 17 Unwrapped harmonic phase response for the Motorola T4500**

For the FV300 radio, at  $f = 800$  MHz,  $\phi_2 = -75^\circ$ , and at  $f = 900$  MHz,  $\phi_2 = -4375^\circ$ . Using a delay of  $1/u_p = 1.27$  ns/ft, as listed in the Megaphase F130 manufacturing specifications,<sup>12</sup> range-to-target may be calculated from the phase response at  $2f$  using Eq. 9:

$$\begin{aligned}
 d &= -\frac{u_p}{2(2)} \left\{ \frac{\phi_2(\omega_2) - \phi_2(\omega_1)}{\omega_2 - \omega_1} \right\} \\
 &= -\frac{1}{4} \cdot \frac{1 \text{ ft}}{1.27 \text{ ns}} \left\{ \frac{\left(-4375^\circ \cdot \frac{\pi}{180^\circ}\right) - \left(-75^\circ \cdot \frac{\pi}{180^\circ}\right)}{(2\pi)(900 \cdot 10^6 \text{ s}^{-1}) - (2\pi)(800 \cdot 10^6 \text{ s}^{-1})} \right\} = 23.5 \text{ ft}
 \end{aligned} \tag{10}$$

With MATLAB, this process can be repeated to generate the distance to each tested target from the phase response of the 2<sup>nd</sup> or 3<sup>rd</sup> harmonic (Table 1).

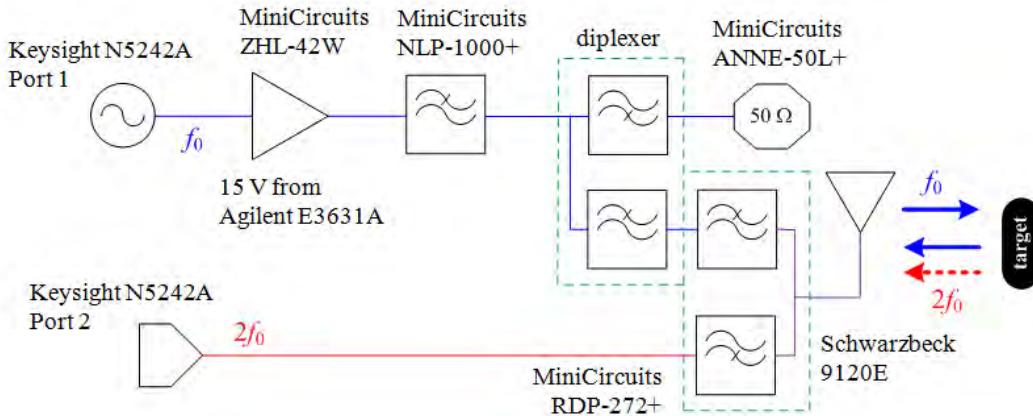

**Table 1 Range-to-target for devices tested in wireline experiment**

Target	<i>M</i>	<i>d</i>	Target	<i>M</i>	<i>d</i>
MiniCircuits ZX60-3011+	2	23.5 ft	MiniCircuits ZFM-2000+	2	23.6 ft
	3	23.4 ft		3	23.7 ft
MiniCircuits ZX60-V63+	2	23.3 ft	Motorola FV300	2	23.5 ft
	3	23.4 ft		3	23.8 ft
MiniCircuits ZLW-186MH	2	23.6 ft	Motorola T4500	2	23.6 ft
	3	23.6 ft		3	23.6 ft
			open circuit	1	23.2 ft

Each distance calculated from the phase data is well within 5% of the actual distance (24 ft), confirming that using harmonic phase information to determine range is a valid technique for use in nonlinear radar.

#### 4. Wireless Experiment

Figure 18 shows the next experimental design used to validate the harmonic phase response, a wireless setup slightly more complex than the wired system previously discussed.

**Fig. 18 Wireless experiment setup**

Like the wireline tests, this experimental design uses the Keysight NVNA to generate the series of transmit signals, as well as receive the harmonic response; though in this wireless configuration, the received signal enters Port 2, instead of returning to the same port, Port 1, as in the previous design. Similar to the wireline tests, the transmission chain begins with signal generation, amplification, and low pass filtering; however, the wireless configuration employs a much more powerful

amp, the MiniCircuits ZHL-42W, with a gain of roughly 38 dB. Again, the low pass filter acts to attenuate harmonics or artifacts that could be generated during amplification. The first major difference between the wired and wireless setups is the next component in the transmitter chain, a configuration of diplexers that serve 3 functions: 1) divert any remaining harmonics that were not sufficiently attenuated by the first filter to a  $50\text{-}\Omega$  load, 2) send the desired, artifact-free signal through another series of filters to the vertically aligned Schwartzbeck 9120E antenna to be transmitted to the target, and 3) on the receive chain, attenuating the received fundamental frequency, while passing the harmonic response to Port 2 of the NVNA to be captured.

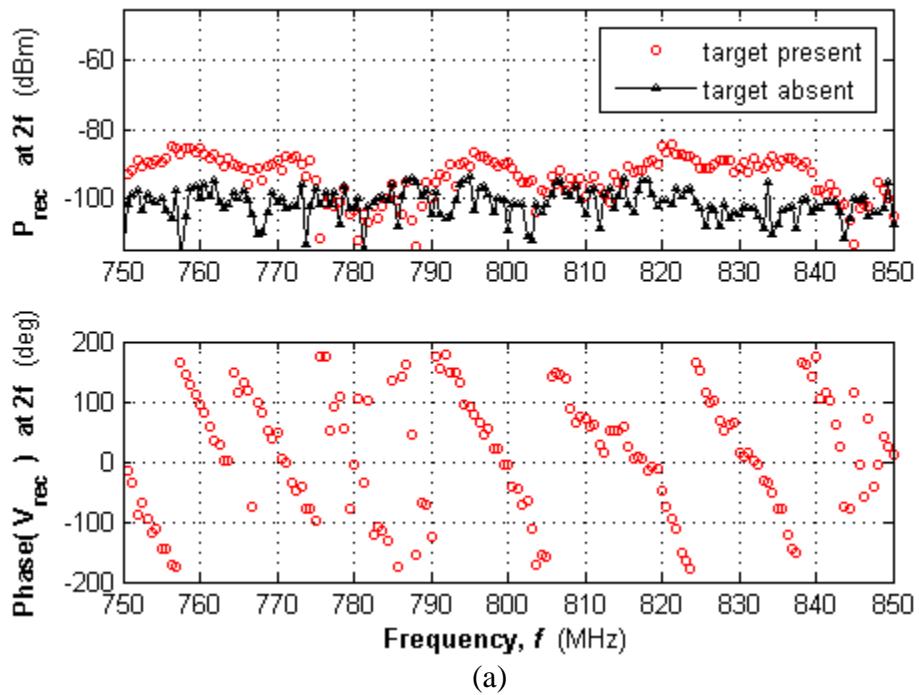

The targets under test for this wireless experiment were the same handheld Motorola radios used in the wireline experiment, the FV300 and T4500. Both targets were powered-on and tested at distances of both 2 and 3 m, directly in front of the antenna. The bandwidth of frequencies the NVNA generates is 750 to 850 MHz with a step of 0.625 MHz, at a power of  $-10\text{ dBm}$ .

The same range equations used to determine distance from phase previously derived and described in Eqs. 8 and 9 can be used in the wireless case, with one small modification. Because of the more complex and thus longer transmitter and receive chains, the time it takes to travel the additional distance to and from the NVNA must be accounted for. This, mathematically, simply translates to a subtraction of  $d_0$ , or the distance that the signal travels from the NVNA's Port 1 to the antenna plus the distance that the harmonic response traverses from the antenna to the NVNA's Port 2, divided in half.

$$d = -\frac{u_p}{2M} \left\{ \frac{\partial}{\partial \omega} \angle \tilde{E}_{\text{rec}} \right\} - d_0 = -\frac{c}{2M} \left\{ \frac{\phi_M(f_2) - \phi_M(f_1)}{2\pi(f_2 - f_1)} \right\} - d_0 \quad (11)$$

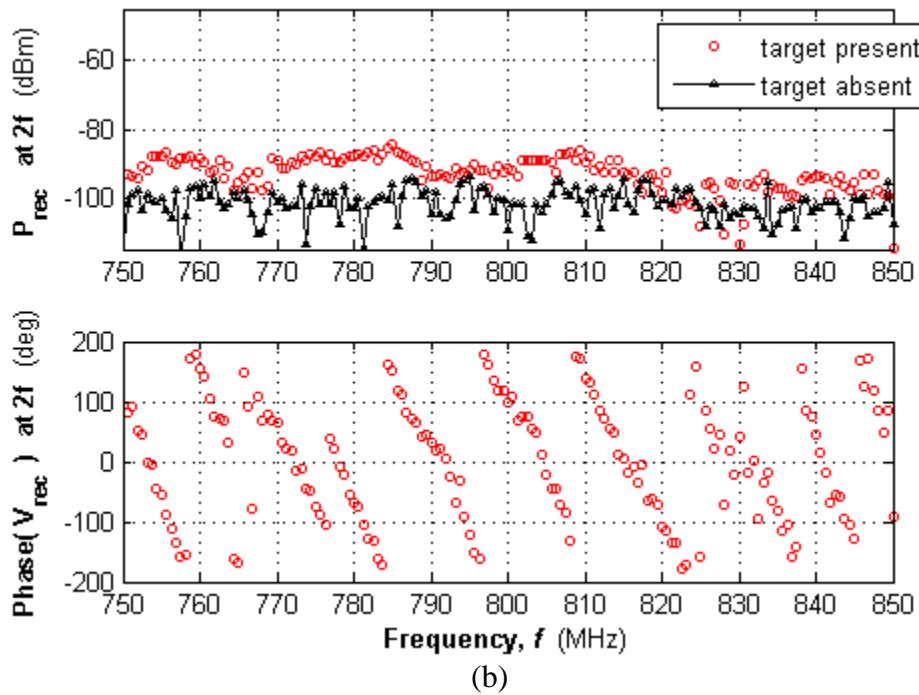

For the radar system used in this experiment, the distance  $d_0$  is 3.2 m. The 2<sup>nd</sup> harmonic response is shown in Fig. 19 for both radios and 2 different distances.

**Motorola T4500 radio, standoff distance  $d = 2$  m**

(a)

**Motorola FV300 radio, standoff distance  $d = 3$  m**

(b)

**Fig. 19** Power and phase of 2<sup>nd</sup> harmonic from the a) Motorola T4500 radio at 2 m away and b) Motorola FV300 radio at 3 m away

Though these data are less strong than their wireline counterpart, range-to-target can still be calculated using Eq. 11, when the target's amplitude response has a sufficient enough signal-to-noise ratio to discern it from the noise floor. Using the 2<sup>nd</sup> harmonic ( $M = 2$ ) reflected from the T4500 radio and data near 760 MHz (the most visibly straight linear portion of the phase plot):

$$\begin{aligned}
 d &= -\frac{u_p}{2(2)} \left\{ \frac{\phi_M(f_2) - \phi_M(f_1)}{2\pi(f_2 - f_1)} \right\} - d_0 \\
 &= -\frac{3 \cdot 10^8 \text{ m/s}}{4} \left\{ \frac{\left(0^\circ \cdot \frac{\pi}{180^\circ}\right) - \left(165^\circ \cdot \frac{\pi}{180^\circ}\right)}{(2\pi)(763.8 \cdot 10^6 \text{ s}^{-1} - 757.5 \cdot 10^6 \text{ s}^{-1})} \right\} - 3.2 \text{ m} = 2.2 \text{ m}
 \end{aligned} \tag{12}$$

The results of the wireless experiment, as shown in Eq. 12, corroborate the data collected in the previous wired experiment. Again, the conjecture that the received harmonics are linear as a function of frequency is verified, so that range can be calculated from the harmonic's phase.

## 5. Conclusions

---

Previous nonlinear harmonic radar systems detect targets via transmission of a single frequency  $\omega$ , stepping (incrementally increasing) this frequency through a wide bandwidth, then listening for a response of the 2<sup>nd</sup> harmonic  $2\omega$ ; however, the phase information that this harmonic contains and its relationship to target distance has been largely assumed and unconfirmed. This assumption was verified through 2 experiments, 1 wired and 1 wireless, where the phase of the 2<sup>nd</sup> and 3<sup>rd</sup> harmonic of the received electromagnetic wave from nonlinear targets was measured and plotted against the frequency. The result was a linear relationship, in which range-to-target could be calculated from slope.
